

**Stat 543 Assignment 9 (Due Monday April 25, 2016)**  
**Asymptotics of "Maximum Likelihood"**

1. (Estimation in a Zero-Inflated Poisson Model) Consider  $n$  iid discrete observations  $X_1, X_2, \dots, X_n$ , each with marginal probability mass function on  $\{0, 1, 2, \dots\}$

$$f(x|p, \lambda) = \begin{cases} p \exp(-\lambda) + (1-p) & x = 0 \\ p \frac{\exp(-\lambda)\lambda^x}{x!} & x = 1, 2, 3, \dots \end{cases}$$

where  $p \in (0, 1)$  and  $\lambda > 0$ . (This marginal is a mixture of a distribution degenerate at 0 and the Poisson ( $\lambda$ ) distribution. It might arise in the inspection for flaws of a mixed lot of items, some of which come from a "perfect" process and others of which come from a process that puts flaws on the items according to a Poisson distribution.)

- (a) Give the likelihood equations for this problem.
- (b) What are the (marginal) large sample distributions of method of moments estimators of  $p$  and  $\lambda$ , say  $\tilde{p}$  and  $\tilde{\lambda}$ , when  $p = .7$  and  $\lambda = 3.0$ ? (Hint: What is the covariance matrix for the vector  $(X_1, X_1^2)'$ ? What, then, does the multivariate central limit theorem say about the large sample joint distribution of  $\sqrt{n} \left( \frac{1}{n} \sum X_i - E_{p,\lambda} X_1, \frac{1}{n} \sum X_i^2 - E_{p,\lambda} X_1^2 \right)'$ ? What, then, does the delta method give you for the large sample joint distribution of  $\sqrt{n} \left( \tilde{p} - .7, \tilde{\lambda} - 3 \right)'$ ?) It may well be useful to know that the first 4 moments of the Poisson distribution are:  $\mu_1 = \lambda$ ,  $\mu_2 = \lambda^2 + \lambda$ ,  $\mu_3 = \lambda^3 + 3\lambda^2 + \lambda$  and  $\mu_4 = \lambda^4 + 6\lambda^3 + 7\lambda^2 + \lambda$ .
- (c) What is the large sample joint distribution of an "MLE" of  $(p, \lambda)$  if  $p = .7$  and  $\lambda = 3.0$ ? How do the marginal distributions compare to those in b)?

Below are  $n = 20$  observations that I simulated from this distribution using  $p = .7$  and  $\lambda = 3.0$ .

0, 3, 2, 5, 3, 4, 0, 0, 4, 0, 0, 5, 3, 5, 5, 4, 2, 0, 1, 2

- (d) Find method of moments estimators based on the data above. Then compute a "one-step Newton improvement" on  $(\tilde{p}, \tilde{\lambda})$ .
- (e) The MLE of  $(p, \lambda)$  based on these data turns out to be  $(\hat{p}, \hat{\lambda}) = (.72675, 3.30242)$ . Find (individual) large sample 90% confidence intervals for  $p$  and  $\lambda$  based on  $(\hat{p}, \hat{\lambda})$  and the observed Fisher information matrix.
- (f) Find an elliptical large sample 90% joint confidence region for  $(p, \lambda)$  based on  $(\hat{p}, \hat{\lambda})$  and the observed Fisher information matrix. Plot this in the  $(p, \lambda)$ -plane.
2. Suppose that for  $\alpha \in [0, 1]$ ,  $X$  is a random variable with probability density

$$f(x|\alpha) = \alpha f_1(x) + (1 - \alpha) f_0(x)$$

where  $f_0(x)$  is the  $N(0, 1)$  density and  $f_1(x)$  is the  $N(1, 1)$  density.

- (a) Find the mean and variance of  $X$ ,  $E_\alpha X$  and  $\text{Var}_\alpha X$ .

- (b) Show that the maximum likelihood estimator of  $\alpha$  based on the single observation,  $X$ , is

$$\hat{\alpha} = \begin{cases} 1 & \text{if } X > .5 \\ 0 & \text{otherwise} \end{cases}$$

Compute the mean and variance of this estimator. Is  $\hat{\alpha}$  unbiased for  $\alpha$ ?

- (c) Argue that the mean squared error of  $\hat{\alpha}$  as an estimator of  $\alpha$  is no more than  $.25 + (.3085)^2$ . Use this fact and compare  $\hat{\alpha}$  and  $X$  in terms of mean squared error.
- (d) Set up an integral giving  $I(\alpha)$ , the Fisher information in  $X$  concerning  $\alpha \in (0, 1)$ .

Now consider estimation of  $\alpha$  based on a sample  $X_1, X_2, \dots, X_n$  that are iid with density (\*). Let  $\hat{\alpha}_n$  be the MLE of  $\alpha$  based on the  $n$  observations and let  $\bar{X}_n$  be the usual sample mean.

- (e) The following figure gives plots of both  $1/I(\alpha)$  and  $1 + \alpha - \alpha^2$ . What does this figure indicate about the the large sample distributions of  $\hat{\alpha}_n$  and  $\bar{X}_n$ ? On the basis of large sample considerations, which of these is the better estimator of  $\alpha$ ? Explain carefully.

fig1

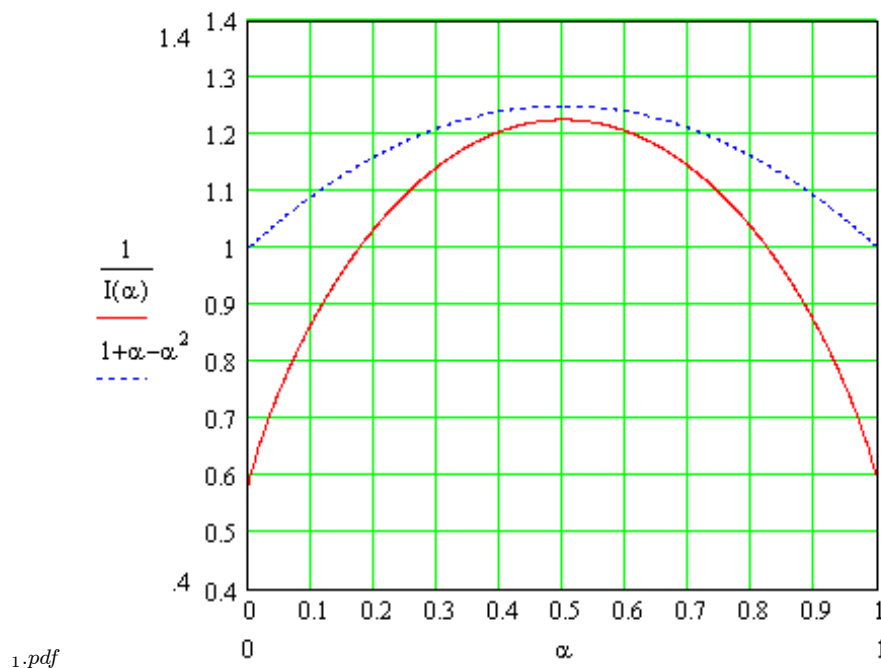

Figure 1:  $1/I(\alpha)$  and  $1 + \alpha - \alpha^2$

- (f) A particular sample of  $n = 20$  observations produces  $\hat{\alpha}_n = .4$ . What is an approximate 90% confidence interval for  $\alpha$  based on the "expected Fisher information" in a single observation? Explain where you are getting your limits.
